The XNA Tools package is included with the MediaPortal package. This is a 2D engine and services package that works with your Content Project, and is designed to greatly simplify development using XNA. The 2D Engine (which is the "middle layer") You can include both the x86 and x64 versions of the 2D engine. You might choose to include only the x86 version when working with a 32-bit system, or only the x64 version when you are targeting a 64-bit system. You can either point to the 2D engine installation by using the RegisterResource line in the main MediaPortal Game class in Program.cs, or you can call the RegisterResource method explicitly on the main class of the project. The following code example is the registration code for the x86 version: This code example is for an x64 system. The x86 version of the 2D engine can be included in any project that uses Content Project, and it does not require that you have the XNA Framework installed. The x64 version works only in projects that have the XNA Framework installed. If you plan to use the XNA Framework to develop applications that run on a 32-bit operating system, you must include the 32-bit x86 version of the 2D engine, since the content project for a Windows 32-bit application is created using a 32-bit SDK. The 2D engine is always included in the Visual Studio solution file. For projects that use the x64 version of the 2D engine, you can also build as a self-contained installation that will not depend on the installed version of the 2D engine. This makes it easy to distribute without the XNA Framework installed. To add a XNA Framework to the solution, first create a reference to the 2D engine in a project that uses the Content Project as you would normally do. Then, in the bin\content project, right-click the References node, and choose Add Reference. Next, choose to add the Microsoft.Xna.Framework.D2D.Graphics.dll file. An assembly reference to the content project in the bin\content project does not add the dll files to the main project bin folder. Instead, a reference to the Content Project in the main project adds the dll files to a bin folder that is in the same folder as the project. (This is true for both the x86 and x64 b7e8fdf5c8
